What Is DNA and Protein Synthesis?

DNA: The Blueprint of Life

Deoxyribonucleic acid (DNA) is the hereditary material in almost all living organisms. It contains the instructions necessary for the growth, development, functioning, and reproduction of cells. DNA molecules are composed of two strands forming a double helix, made up of four nucleotide bases: Adenine (A) Thymine (T) Cytosine (C) Guanine (G) The sequence of these bases encodes genetic information, which is organized into units called genes.

Protein Synthesis: From Genes to Proteins

Protein synthesis is the biological process through which cells construct proteins based on the genetic instructions encoded in DNA. This process involves two main stages: 1. Transcription — the process of copying a gene's DNA sequence into messenger RNA (mRNA). 2. Translation — the decoding of mRNA to assemble amino acids into a specific protein. This process is fundamental to all living organisms, enabling cells to produce the proteins necessary for various functions, including enzyme activity, structural components, and signaling.
